Try it Yourself »

Example

Floats:

```
x = float(1)      # x will be 1.0
y = float(2.8)    # y will be 2.8
z = float("3")    # z will be 3.0
w = float("4.2")  # w will be 4.2
```

Try it Yourself »

Example

```
x = 5
y = "John"
print(x)
print(y)
```

Try it Yourself »

Variables do not need to be declared with any particular *type*, and can even change type after they have been declared.

Example

```
x = 4              # x is of type int
x = "Sally"        # x is now of type str
print(x)
```

```
x = 4
x = "Sally"
print(x)
```

Sally

Python Numbers

There are three numeric types in Python:

- `int`
- `float`
- `complex`

Variables of numeric types are created when you assign a value to them:

Example

```
x = 1 # int
y = 2.8 # float
z = 1j # complex
```

Get your own Python Serv

To verify the type of any object in Python, use the `type()` function:

Example

```
print(type(x))
```

Example	Data Type	Try it
x = "Hello World"	str	Try it »
x = 20	int	Try it »
x = 20.5	float	Try it »
x = 1j	complex	Try it »
x = ["apple", "banana", "cherry"]	list	Try it »
x = ("apple", "banana", "cherry")	tuple	Try it »
x = range(6)	range	Try it »
x = {"name" : "John", "age" : 36}	dict	Try it »
x = {"apple", "banana", "cherry"}	set	Try it »
x = frozenset({"apple", "banana", "cherry"})	frozenset	Try it »
x = True	bool	Try it »
x = b"Hello"	bytes	Try it »

Exercise?

If `x = 5`, what is a correct syntax for printing the data type of the variable `x`?

☐ `print(dtype(x))`

☐ `print(type(x))`

☐ `print(x.dtype())`

Submit Answer »

Exercise: Python Data Types
